

Flex Based Fuel Cell

Technical Field

The technical field is fuel cells, with or without proton exchange membranes.

Background

A fuel cell is an electrochemical apparatus wherein chemical energy generated from a combination of a fuel with an oxidant is converted to electric energy in the presence of a catalyst. The fuel is fed to an anode, which has a negative polarity, and the oxidant is fed to a cathode, which, conversely, has a positive polarity. The two electrodes are connected within the fuel cell by an electrolyte to transmit protons from the anode to the cathode. The electrolyte can be an acidic or an alkaline solution, or a solid polymer ion-exchange membrane characterized by a high ionic conductivity. The solid polymer electrolyte is often referred to as a proton exchange membrane (PEM).

In fuel cells employing liquid fuel, such as methanol, and an oxygen-containing oxidant, such as air or pure oxygen, the methanol is oxidized at an anode catalyst layer to produce protons and carbon dioxide. The protons migrate through the PEM from the anode to the cathode. At a cathode catalyst layer, oxygen reacts with the protons to form water. The anode and cathode reactions in this type of direct methanol fuel cell are shown in the following equations:

The essential requirements of typical fuel cells (see, e.g., Figure 1) include: first, the fuel cell requires efficient delivery of fuel and air to the electrode, which typically requires complicated microchannels and plumbing structures. A second requirement is that the fuel cell should provide easy access to the catalyst and a large surface area for reaction. This second requirement can be satisfied by using an electrode made of an electrically conductive porous substrate that renders the electrode permeable to fluid reactants and products in the fuel cell. To increase the surface area for reaction, the catalyst can also be filled into or deposited onto a porous substrate. However, these modifications result in a fragile porous electrode that may need additional mechanical support, such as by use of a fiber matrix. Alternatively, the electrode can be made of an

1 etched porous Vycor glass substrate or an etched-nuclear-particle-track membrane
2 substrate to improve its toughness and strength. A third requirement is close contact
3 between the electrode, the catalyst, and the PEM. The interface between the electrode
4 and PEM is a discontinuity area as concerns the electric current transmission wherein the
5 charge carriers are the electrons, on one side, and the protons on the other side. A
6 solution to this problem has been attempted by hot pressing of the electrodes onto the
7 PEM (U.S. Patent No. 3,134,697). Another solution suggests the intimate contact of
8 the catalytic particles with a protonic conductor before interfacing the electrode with the
9 electrolyte (U.S. Patent No. 4,876,115). Other solutions are described in U.S. Patent
10 Nos. 5,482,792 and 6,022,634. A fourth requirement is that the fuel cell should provide
11 for humidity control of the electrode. The PEM requires water to be effective in
12 conducting proton. However, since it operates at a higher temperature than its
13 surroundings, the PEM tends to dehydrate during operation. The typical method of re-
14 hydrating the PEM is to capture water in the exhaust stream and circulate it back to the
15 PEM.

16 **Summary**

17 A flex based fuel cell comprises two flex circuits assembled face-to-face with
18 PEM layers in between. Each flex circuit includes layers of a flex substrate, a patterned
19 conductive material, a porous material sheet with a catalyst coating, and a PEM.

20 The catalyst coating on the porous material provides a large surface area for
21 chemical reactions to proceed and small gaps in the porous material deliver liquid fuel to
22 the catalyst through capillary force. The support of a soggy PEM on a porous electrode
23 may be achieved by assembling two flex substrates face-to-face with the PEM
24 constrained between the two flex substrates.

25 The flex substrates can bend in such a fashion to form a closed structure for
26 confining the fuel. The delivery of the fuel can then be achieved by capillary force of a
27 porous material sheet with the fuel distributed uniformly to all active surfaces, as long as
28 a portion of the porous material sheet is in contact with the liquid fuel. Microchannels
29 and plumbing are not required.

1 The flex based fuel cell can confine water between the two flex substrates to
2 provide moisture for the PEM. Since deionized water can easily conduct protons but
3 not electrons, a fuel cell can be constructed without the PEM. Two flex substrates
4 without the PEM layer can be bonded together face-to-face with an adhesive layer in
5 between as ridges.

6 The flex substrate, such as one using Kapton, provides additional advantages.
7 The electrodes can be patterned directly on the flex substrate, thereby connecting
8 different fuel cell panels in either serial or parallel manner.

9 In an embodiment, the flex substrates are formed into a cylinder. The interior
10 side of the cylinder would be the fuel side, and the exterior of the cylinder would be the
11 oxygen side. The fuel cell can be sealed at the bottom of the cylinder to provide a
12 container for the liquid fuel. The liquid fuel, such as methanol, is delivered by the porous
13 metal to the active catalytic surface of the interior side. Protons generated in the cylinder
14 interior then diffuse through the PEM and reach the catalytic surface on the exterior side
15 of the cylinder, where the protons combine with oxygen. The exterior side of the fuel
16 cell is open to the atmosphere, which serves to supply the oxygen to the cylinder and
17 carry away the reactant water vapor.

18 The flex substrates can be manufactured by the following steps:

19 (1) Patterning the flex substrate, such as Kapton (Dupont) or Upilex (Ube), with
20 a thin film of conductive material. The patterning of the thin film provides the
21 flexibility to define the size of fuel cell panels, as well as to configure the fuel cell
22 for any particular current density or voltage output by routing the thin film
23 patterning appropriately.

24 (2) Attaching a porous material sheet to the patterned thin film on the flex. In an
25 embodiment, the porous material may be a porous metal. Alternatively, other
26 porous materials may be used. For example, an organo-metallic solgel material
27 may be attached to the patterned thin film. The attachment step can be
28 accomplished by either attaching a commercially available porous metal sheet on
29 the flex, or sintering a thick layer of porous metal on the flex. A thick porous
30 metal layer can also be manufactured by applying a paste of low temperature

10006771-1

1 metal powder, such as zinc nano particles (Aldrich catalog # 48,393-1) mixed in
2 glycol, and baking the resulting assembly in an oven to dry out the glycol and
3 partially melt the metal particles. The metal powder paste can be screen printed
4 on the flex substrate so that the location and shape of the sintered porous metal
5 can conform to the thin film electrode previously patterned on the flex substrate.
6 As an alternative to the zinc powdered metal, silver powder may be used.

7 (3) Depositing a catalytic coating on the porous material sheet. Several catalytic
8 materials, such as Pt-Ru and Pt-Ru-Os, are effective in converting methanol to
9 proton without poisoning platinum in the flex substrate.

10 (4) Ablating backside openings to allow access to the catalytic surfaces. The
11 flex substrate is ablated with a laser from the backside to create openings so that
12 fuel on the cathode side and oxygen on the anode side can reach the active
13 catalytic surfaces through the openings and the porous metal layer.

14 (5) For those flex substrates with a PEM, the surface of the catalytic coating
15 may then be coated with a thin layer of PEM by dipping the structure into a 5%
16 Nafion solution. A thin layer of PEM on top of the catalyst surface helps to
17 capture protons. The thickness of the PEM may be controlled so that the liquid
18 fuel can readily diffuse through the thin layer.

19 Two flex substrates can then be assembled face-to-face with the PEM in
20 between to form a flex based fuel cell. For fuel cells without the PEM, two flex circuits
21 manufactured with only the first four steps (without the PEM coating step) are assembled
22 face-to-face with the catalytic coating layer in between.

Description of the Drawings

The detailed description will refer to the following drawings, in which like numerals refer to like elements, and in which:

Figure 1 illustrates a prior art fuel cell assembly;

Figure 2 shows a cross section of a flex based fuel cell having two flex circuits assembled face-to-face with a proton exchange membrane PEM in between;

Figures 3A and 3B show a top sectional view and a plan view of the fuel cell assembly;

Figure 4 shows a flex based cylindrical fuel cell assembly;

Figures 5A - 5E show a process for manufacturing the flex based fuel cell; and

Figure 6 shows an alternative flex based fuel cell.

Detailed Description

Figure 2 is a simplified cross-section view showing an exemplary flex based fuel cell 100. The fuel cell 100 includes a right flex circuit A and a left flex circuit B. This naming convention is purely arbitrary and is used to add greater clarity to the description of the flex based fuel cell 100. Two flex substrates 101 and 102 are assembled face-to-face together with a PEM 103 in between. On either side of the PEM 103 are porous material and catalyst layers 104. Adjacent to the PEM 103 is a palladium (Pd) layer 105 that prevents cross-over of the methanol fuel. Adjacent to the porous material and catalyst layers 104 are anode and cathode electrodes (conductors) 106 and 107. A dry film adhesive 108 serves to separate portions of the fuel cell 100. Recycled water 109 flows through the fuel cell 100, as shown. A liquid fuel 110, such as methanol, for example, is provided on the anode side of the fuel cell 100. Air and water vapor 111 flow past the cathode electrode 107. The methanol fuel 110 has direct contact with the porous material layers 104 through openings 112 in flex substrates 101, 102. The methanol fuel 110 is delivered by the porous material layers 104 to an active catalytic surface 105 where CH_3OH reacts with H_2O (methanol) to form CO_2 and protons. The protons then diffuse through the PEM layer 103 and reach a catalytic layer 107, where the protons combine with oxygen to form H_2O . The left flex circuit B of the fuel cell 100

1 is open to the atmosphere, which serves to supply the oxygen to the fuel cell, and carry
2 away the reactant water vapor 111.

3 In an embodiment, the porous material layers 104 are formed of a porous metal
4 material such as zinc or silver powder. The porous metal layers 104 deliver the liquid
5 fuel (methanol) 110 by means of capillary action. Capillary action depends on the fact
6 that a liquid near a solid wall will undergo curvature of the liquid surface. The amount of
7 curvature depends on the difference between surface tension of the solid-vapor film
8 (S_{LV}) and surface tension of the solid-liquid film (S_{JV}). Depending on the liquid and the
9 solid, the curvature can be positive, negative or zero. In the case of a liquid such as
10 methanol that wets the pores in the porous metal layer 104, the methanol will rise in the
11 pores until an equilibrium height y is reached:

$$y = \frac{2S_{LV} \cos \theta}{\rho g r}$$

13 where:

14 r = radius of pores

15 θ = contact angle of the liquid methanol the pores.

16 Thus, by careful design, the liquid fuel (methanol) 110 can be made to supply all
17 portions of the fuel cell 100 without elaborate pumps and plumbing. Note that pores in
18 the porous metal layer 104 may be oriented in the local plane, or substantially in the local
19 plane defined by the flexible substrates 101, 102. The pores may be further oriented
20 such that liquid fuel will be transported in a specified direction (e.g. vertically) within the
21 porous metal layer 104 so that liquid fuel reaches all, or substantially all, of the fuel side
22 flex circuit A (see Figure 2).

23 As shown in Figures 3A and 3B, two or more fuel cells 100 can be bonded
24 together in such a way that there is an enclosed space 120 between two fuel cells 100.
25 The enclosed space 120 is filled with water or a water containing solution to provide
26 moisture for the PEMs, which require water to be effective in conducting protons.

27 As shown in Figure 4, a flex fuel cell assembly 130 can be shaped into the form
28 of a cylinder. An interior 131 of the cylinder would be the fuel side, and an exterior 132

1 of the cylinder would be the oxygen side. The fuel cell can be sealed at a top 133 and a
2 bottom 134 of the cylinder interior 131 to provide a container for the liquid fuel.
3 Alternatively, the cylinder top may be left unsealed. In an additional embodiment, liquid
4 fuel may be supplied to the exterior 132 of the flex fuel assembly 130.

5 In addition to the non-planar cylindrical shape shown in Figure 4, the flex fuel
6 cell assembly 130 may be shaped into other non-planar and substantially non-planar
7 shapes, including a polygon of N sides, a star having M points, where M may be the
8 integer 5 or larger, and an oval, for example. The flex fuel cell assembly 130 may also
9 be formed in a shape of a cross or other non-planar or substantially non-planar form.
10 These complex shapes have the advantage of increasing the surface area for fuel cell
11 reactions and power production.

12 Because the flex fuel assembly 130 can be molded to a variety of shapes, the
13 flex fuel assembly 130 is ideal for power applications that are constrained in size and
14 shape. Thus, a fuel cell system using the flex fuel assembly 130 can be shaped to fit
15 virtually any container or enclosure, allowing the fuel cell system to be used in a wide
16 variety of applications where prior art fuel cell systems would not be useable.

17 Wrapping a flex substrate into the cylindrical shape as shown in Figure 4 has the
18 added advantage of enhancing the adhesive effect between the Nafion and the flex
19 substrates. The enhanced adhesive effect occurs primarily because of the compressive
20 forces acting on the Nafion by the cylindrical flex substrates.

21 As noted above, the flex-based fuel cell 100 shown in Figure 2, as well as other
22 embodiments, such as the cylindrical fuel cell 130 shown in Figure 4, may use capillary
23 action to draw liquid fuel, such as methanol, to all active regions of the fuel cell. The rate
24 of capillary action may be controlled by adjusting the pore size (diameter) of pores in the
25 porous metal and catalytic layers 104. Using capillary action to move the liquid fuel
26 through the fuel cell 100 allows the fuel cell 100 to operate without expensive and bulky
27 pumps, valves and piping, thereby making the fuel cell lighter and more desirable for
28 portable power applications.

29 Figures 5A-5E depict processing steps for manufacturing the flex circuits. As
30 shown in Figure 5A, which includes a plan view and a side view, the first step is to

metallize a flex substrate 150, using a material such as Kapton or Upilex, to form a thin film electrode 151 in a predetermined pattern. The patterning of the thin film electrode 151 defines the size of the cell panels, and configures the fuel cell for any particular current density or voltage output.

The next step, as shown in Figure 5B (which includes plan and side views), is to attach a porous metal layer 152 to the patterned thin film electrode 151 on the flex substrate 150. The porous metal layer 152 can be a commercially available porous metal sheet. Alternatively, a thick porous metal layer can be sintered on the flex. Referring to Figure 5B, a paste of low temperature metal powder such as zinc nano particles mixed in glycol, is applied on top of the thin film electrodes 151. Alternatively, silver powder may be used. The flex substrate 150 is then baked in an oven to dry out the glycol and partially melt the metal particles to form a thick layer of porous metal. The metal powder paste also may be screen printed on the flex substrate 150 so that the location and shape of the sintered porous metal can conform to the thin film electrode 151 previously patterned on the flex substrate 150.

The next step, as shown in Figure 5C (including plan and side views), is to deposit a layer 153 of catalytic coating on the porous metal layer 152. Referring to the composition of catalytic coating for fuel cells using methanol, catalytic materials such as Pt-Ru and Pt-Ru-Os, are found to be effective in converting methanol to protons without poisoning other fuel cell constituents.

The next step, as shown in Figure 5D (again showing plan and side views), is to laser ablate backside openings 154 on the flex substrate 150 and the thin film electrodes 151, so that the fuel or oxygen can reach the active catalytic layer 153 through openings in the flex substrate 150 and the porous metal layer 152.

The final step, as shown in Figure 5E (plan and side views), is to cover the surface of the catalytic layer 153 with a thin layer of PEM 155. In a preferred embodiment, the flex structure is dipped into a 5% Nafion solution. A thickness of the PEM 155 should also be controlled so that the liquid fuel can diffuse through this thin layer.

1 Figure 6 illustrates an alternative embodiment of a flex circuit for use in a flex
2 based fuel cell. The flex based fuel cell includes a plurality of flex circuits. A flex circuit
3 200 includes a right, or fuel-side flex circuit C and a left, or air-side flex circuit D. This
4 naming convention is purely arbitrary and is used to add greater clarity to the description
5 of the flex circuit 200.

6 The flex circuit 200 includes flex substrates 201 and 202, each having openings
7 212. In immediate contact with the flex substrates 201 and 202 are conductors 206 and
8 207. Adjacent the conductors 206, 207 are porous metal and catalyst layers 204. In an
9 embodiment, the catalyst may be Pt-Ru or Pt-Ru-Os. The porous metal may be chosen
10 so that the pores in the porous metal provide a capillary action that draws fuel into the
11 flex circuit 200. An adhesive 208 may be used to seal the space between the porous
12 metal and catalyst layers 204.

13 A liquid fuel 210, such as methanol, is supplied at the right side C of the flex
14 circuit 200. Air and water 211 are removed at the left side D of the flex circuit 200.

15 In a departure from other fuel cell designs, the flex circuit 200 does not use a
16 PEM. Instead, a thin layer 209 of dionized water is maintained between the porous
17 metal and catalyst layers 204. By maintaining a spacing between the porous metal and
18 catalyst layers 204, the flex circuit 200 is able to generate protons from the liquid fuel
19 210 and the protons are combined with oxygen to form water. That is, the dionized
20 water conducts protons but does not conduct electrons. Thus, by eliminating the PEM,
21 the flex circuit 200 shown in Figure 6 is less costly to build.

22 Although preferred embodiments and their advantages have been described in
23 detail, various changes, substitutions and alterations can be made herein without
24 departing from the spirit and scope of the flex based fuel cell as defined by the appended
25 claims and their equivalents.
